## Televideo Terminal Emulators for the Macintosh

This article last reviewed: 23 May 1989

As of May 1989, the only Televideo terminal emulation packages for the Macintosh are for the Televideo 950 and the Televideo 925. The Televideo 924 was not in evidence. Palantir's "InTalk" package for 925 emulation did not work.

However, if you need to log onto a Honeywell host that requires the Televideo 924, you can use the Telescope programmable terminal emulation package, you can program in the escape sequences for the 924. The emulation works fine except for one thing: Telescope has no facilities for video attributes, such as half-bright, colors, blinking, underlines, and so on.

Telescope uses the standard Macintosh two-bit video display. This setup makes programming intensity and color impossible. Supposedly, the package supports underlines, but not flashing characters. Intensity and color are available on the Macintosh II display, but new software will have to be written specifically for the system.
