PrintMonitor: Troubleshooting Quit Unexpectedly (3)

This article last reviewed: 15 July 1990

TOPIC ---

When printing to a LaserWriter in MultiFinder with Background Printing on,
the PrintMonitor will either "Quit Unexpectedly(3)" or just not print.

The files I'm trying to print remain in the Spool Folder with the
PrintMonitor appearing every 10 seconds to announce that it has "Quit
Unexpectedly(3)". This keeps happening until PrintMonitor is removed from
the System folder or the spool files are removed from the Spool folder.

Also, the PrintMonitor "Quits Unexpectedly(3)" when I double click on it.

DISCUSSION ---

Most often, applications unexpectedly quit because they ask for more memory
than has been allocated to them, the Memory Manager says "no", and the
application has no idea what to do next.

PrintMonitor, even though it looks like a standalone application, does not
use the RAM allocated to it during the background printing process.
Instead, PrintMonitor uses some of the RAM allocated to the Finder. If the
Finder (in the background) is maintaining a lot of items, such as open
windows, mounted file server volumes, and so on, there may not be enough
RAM left over for PrintMonitor to work. Try allocating more memory to
Finder, such as 320K (the default is 160K).

Another possible problem is a corrupted Backgrounder file, the INIT that
handles the background task management. Since PrintMonitor is appearing
periodically to check the Spool Folder, it's probable that Backgrounder is
fine and you're seeing only a memory limitation.

And finally, there may be an INIT that is conflicting with PrintMonitor's
operation. Removing all non-essential INITs and testing will tell you if
that's the problem.
